# Calibrated Multiport Large-Signal Measurement Setups for Outphasing, Doherty and Load Modulated Balanced Power Amplifiers

<sup>1</sup> Tibault Reveyrand,

<sup>1</sup> Pierre Medrel, <sup>1</sup> Jean-Michel Nébus, and <sup>2</sup> Zoya Popović

<sup>1</sup> XLIM-CNRS, <sup>2</sup> CU-Boulder

# Main challenges in PA design

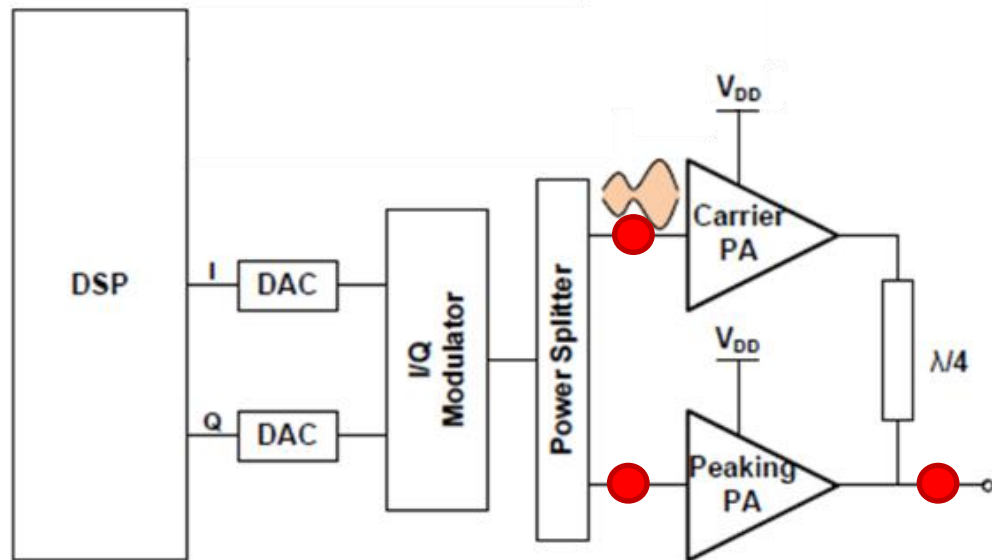

- Communications signals increasingly complex and broadband
- Signals vary in both amplitude and phase – PAPR, PDF and CCDF criteria
- It is difficult to transmit such signal with high efficiency transmitters

- Efficiency drops as output power drops
- Efficient PAs are nonlinear
- Output Load can vary

# Doherty Amplifier

**W. Doherty**, "A new high efficiency power amplifier for modulated waves," *Proc. IRE*, vol. 24, no. 9, pp. 1163–1182, Sep. 1936.

From B. Kim et al, 2010

# Load Modulated Balanced Amplifier

**Daniel J. Shepphard, Jeffrey Powell, and Steve C. Cripps**, "An Efficient Broadband Reconfigurable Power Amplifier Using Active Load Modulation," *IEEE Microwave and Wireless Components Letters*, vol. 26, no. 6, pp. 443–445, May 2016.

# Outphasing Amplifier

H. Chireix, "High power outphasing modulation," *Proc. IRE*, vol. 23, no. 11, pp. 1370–1392, Nov. 1935

- Amplitude modulation converted to additional phase modulation
- High-efficiency PAs driven with constant envelope
- Combiner reconstructs envelope through vector addition
- Combiner can be isolated or non-isolated

# Main challenges in PA design

Digital dual input PAs add another degree of freedom to the sub-system to optimize :

- the Linearity / Efficiency trade-off ;
- the design of the input combiner or driver for a RF power amplifier ;
- the Digital Pre Distortion (DPD).

NEED FOR  
MULTIPORT CALIBRATED NONLINEAR MEASUREMENTS

# 1-Port CW Power Calibration

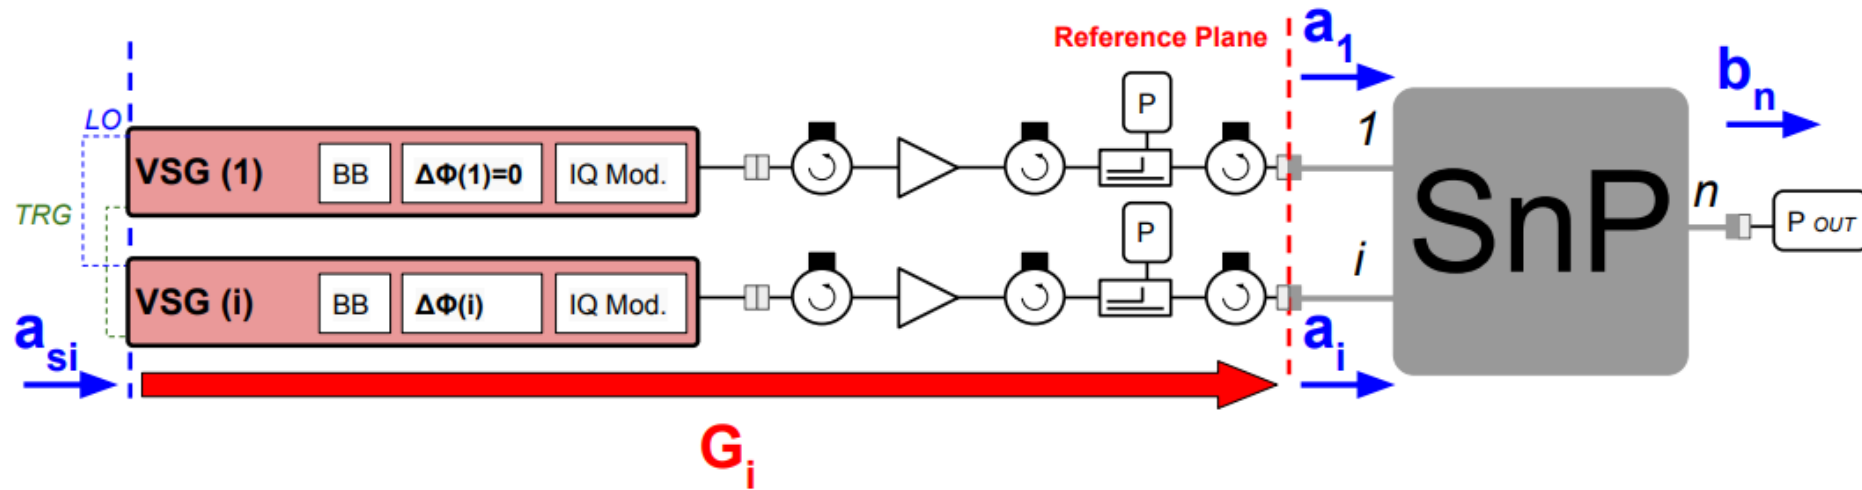

- CW signal can be obtained from a time constant complex envelope. Control of the phase of the carrier (LO) is performed by applying a phase offset on the frequency domain IQ modulation. This phase control is essential for the "Multiport Source".
- Magnitude calibration procedure consists in identifying  $|G_1|^2 = \Delta P = \frac{P_{DUT}}{P_{SOURCE}}$ .

# Principle of a Multi-source Calibration

# Multi-source Calibration

$$b_n = S_{n1} \cdot a_1 + S_{ni} \cdot a_i$$

$$|b_n|^2 = |S_{n1} \cdot a_1 + S_{ni} \cdot G_i \cdot a_{si}|^2$$

$$A \cdot |G_i|^2 + B \cdot \Re\{G_i\} + C \cdot \Im\{G_i\} = D$$

with

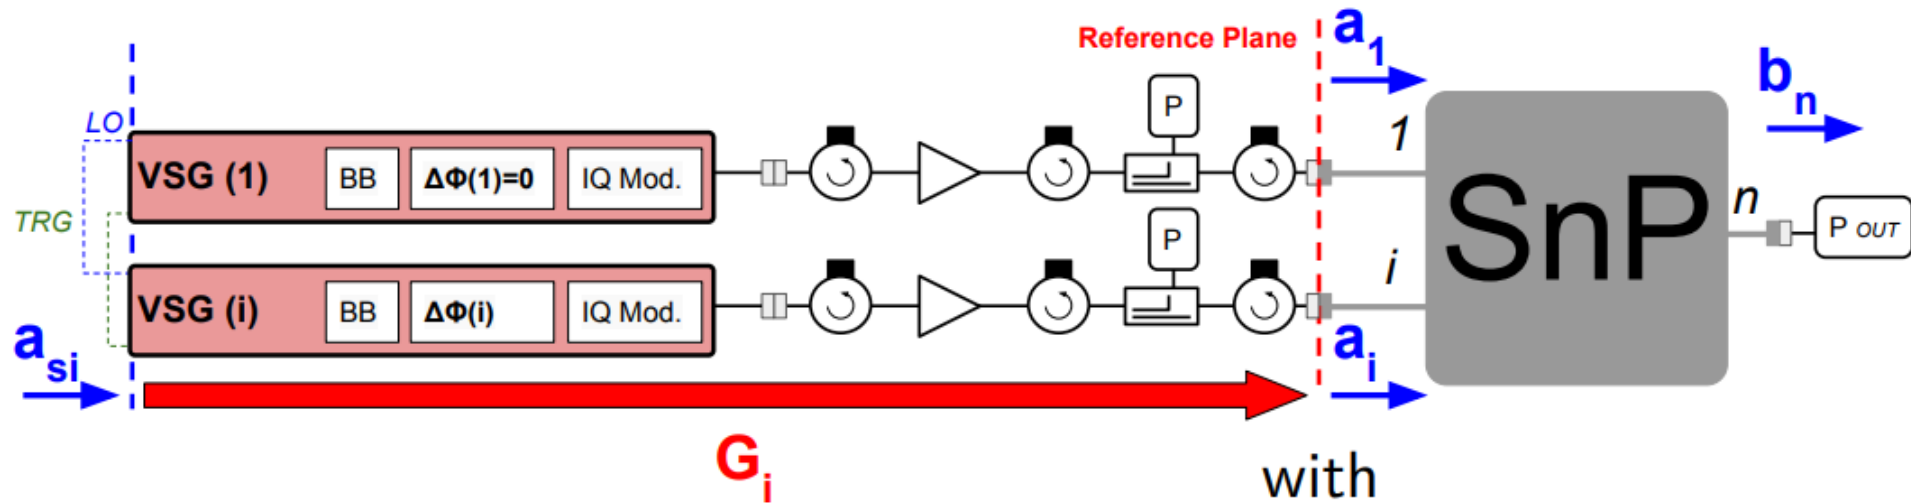

$$A = |S_{ni} \cdot a_{si}|^2$$

$$B = 2 \cdot \Re\{S_{n1}^* \cdot a_1^* \cdot S_{ni} \cdot a_{si}\}$$

$$C = -2 \cdot \Im\{S_{n1}^* \cdot a_1^* \cdot S_{ni} \cdot a_{si}\}$$

$$D = |b_n|^2 - |S_{n1} \cdot a_1|^2$$

# Multi-source Calibration

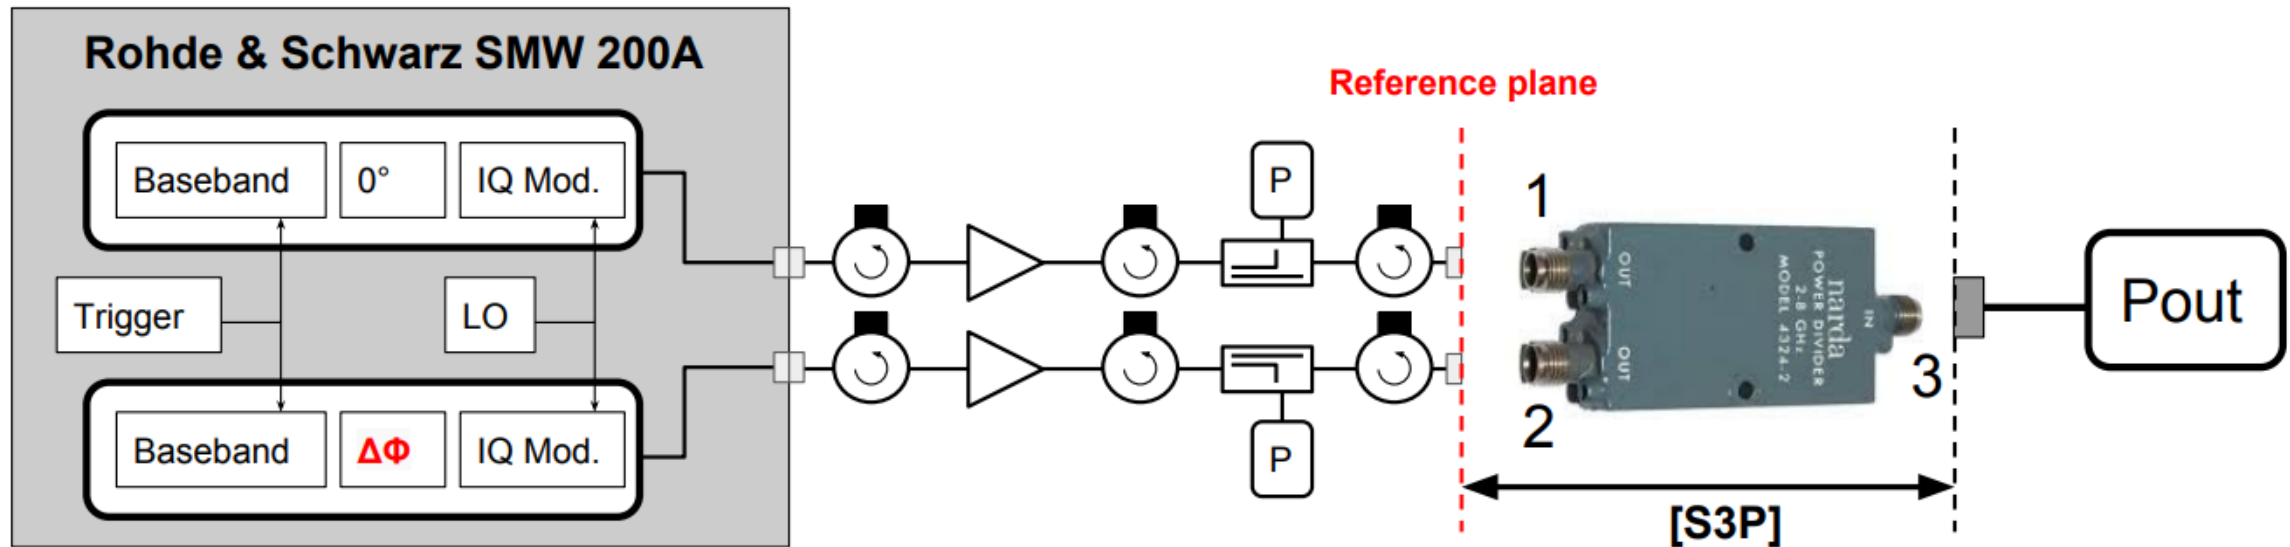

$$\begin{pmatrix} |G_i|^2 \\ \Re\{G_i\} \\ \Im\{G_i\} \end{pmatrix} = \begin{bmatrix} A(\phi_A) & B(\phi_A) & C(\phi_A) \\ A(\phi_B) & B(\phi_B) & C(\phi_B) \\ A(\phi_C) & B(\phi_C) & C(\phi_C) \\ \vdots & \vdots & \vdots \end{bmatrix}^{\dagger} \cdot \begin{pmatrix} D(\phi_A) \\ D(\phi_B) \\ D(\phi_C) \\ \vdots \end{pmatrix}$$

where  $\bullet^{\dagger}$  denotes the pseudo-inverse operator.

$$\begin{aligned} A &= |S_{ni} \cdot a_{si}|^2 \\ B &= 2 \cdot \Re\{S_{n1}^* \cdot a_1^* \cdot S_{ni} \cdot a_{si}\} \\ C &= -2 \cdot \Im\{S_{n1}^* \cdot a_1^* \cdot S_{ni} \cdot a_{si}\} \\ D &= |b_n|^2 - |S_{n1} \cdot a_1|^2 \end{aligned}$$

# Multi-source Calibration Validation

- **Uncalibrated phase:**  $\text{Arg}\{a_2\} = \Delta\Phi$  is entered in the instrument ;
- **Calibrated phase:**  $\text{Arg}\{a_2\} = \Delta\Phi$  is referenced at the DUT reference plane. The instrument value takes into account the phase shift between the digital command and the RF reference plane ;
- **Simulation:**  $\text{Arg}\{a_2\} = \Delta\Phi$  is calculated from the measured powers and the S3P file assuming  $\text{Arg}\{a_1\} = 0$ .

# Multi-source Calibration Validation

## Measurements:

Uncalibrated phase  
Calibrated phase

## Simulation:

$\Delta\Phi$  calculated from  
*Pin1, Pin2, Pout and S3P file*

# Digital Doherty CW Measurements

# Digital Doherty Measurements

$P_{in}$  is the available power at the input of the **Main** amplifier.

We focus on the magnitude and phase imbalance between the two inputs.

$\Delta P$  and  $\Delta\varphi$  are swept for each value of  $P_{in}$

Then, we can sort out the best digital control of the Doherty in term of:

- **efficiency** ;
- **linearity**.

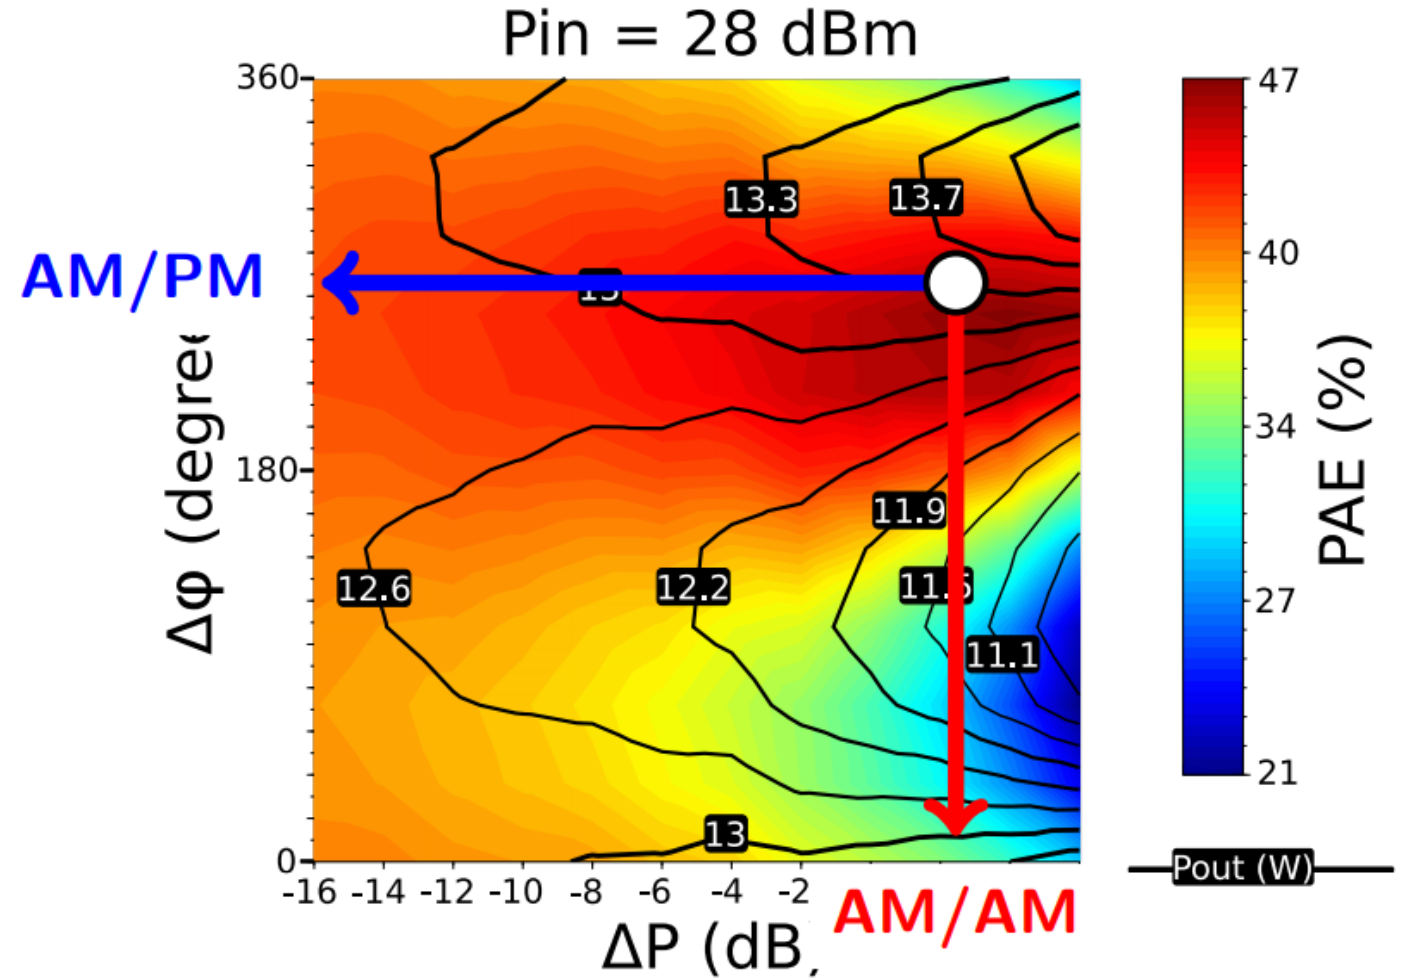

# LMBA Measurements

# Digital LMBA CW Measurements

- Direct performance plot at each CW input power ;
- Investigate internal Load-Pull effect ;
- Visual extraction of **AM/AM** and **AM/PM** of the RF auxiliary path according to the selected trade-off.

## Two-Port Network Analyzer Calibration Using an Unknown “Thru”

Andrea Ferrero, *Member, IEEE*, and Umberto Pisani

**Abstract**—A procedure performed by using a generic two port reciprocal network instead of a standard *thru* in a full two-port error correction of an automatic network analyzer is presented. Although it can be applied to any type of waveguide system the proposed technique is particularly useful with noninsertable coaxial or on-wafer devices. Experimental comparisons show that the suggested procedure provides a great degree of accuracy.

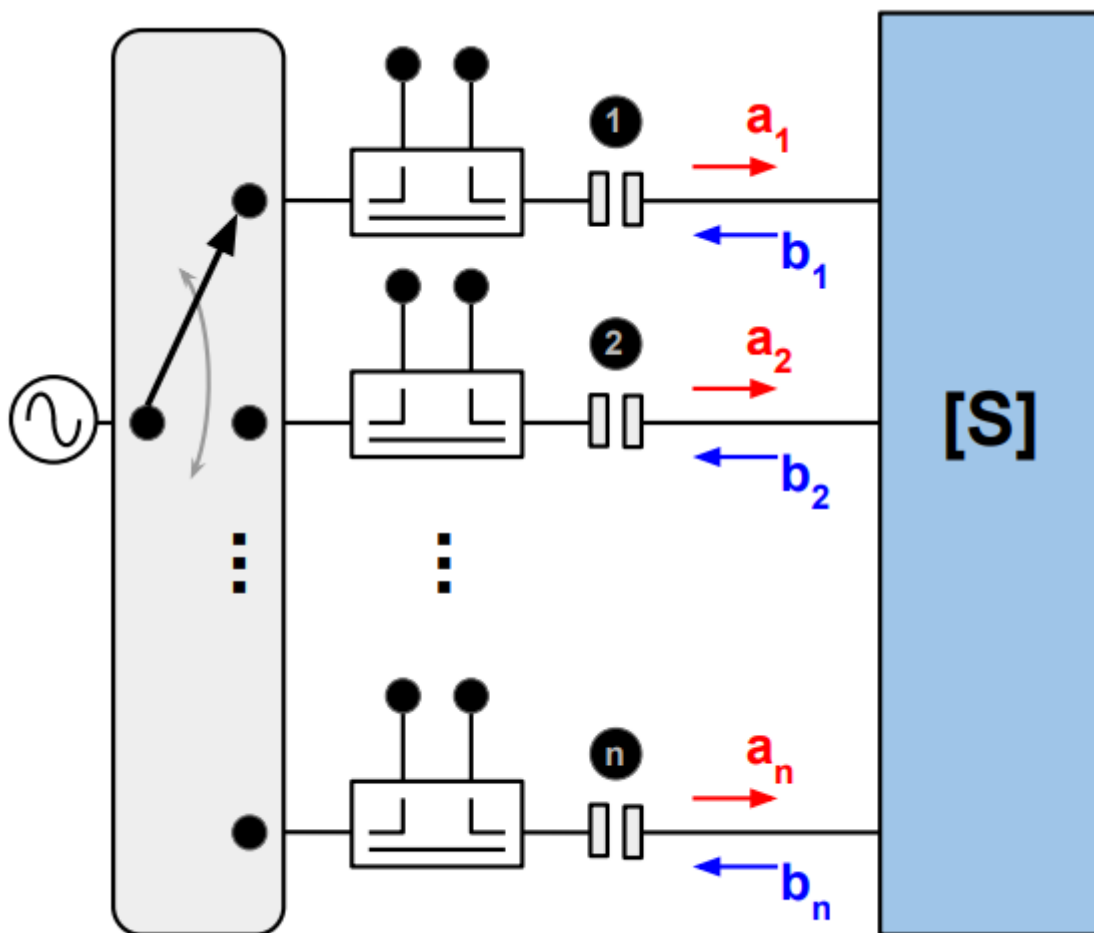

Fig. 1. Error box NWA model.

### I. INTRODUCTION

# SOLR for multiport NVNAs

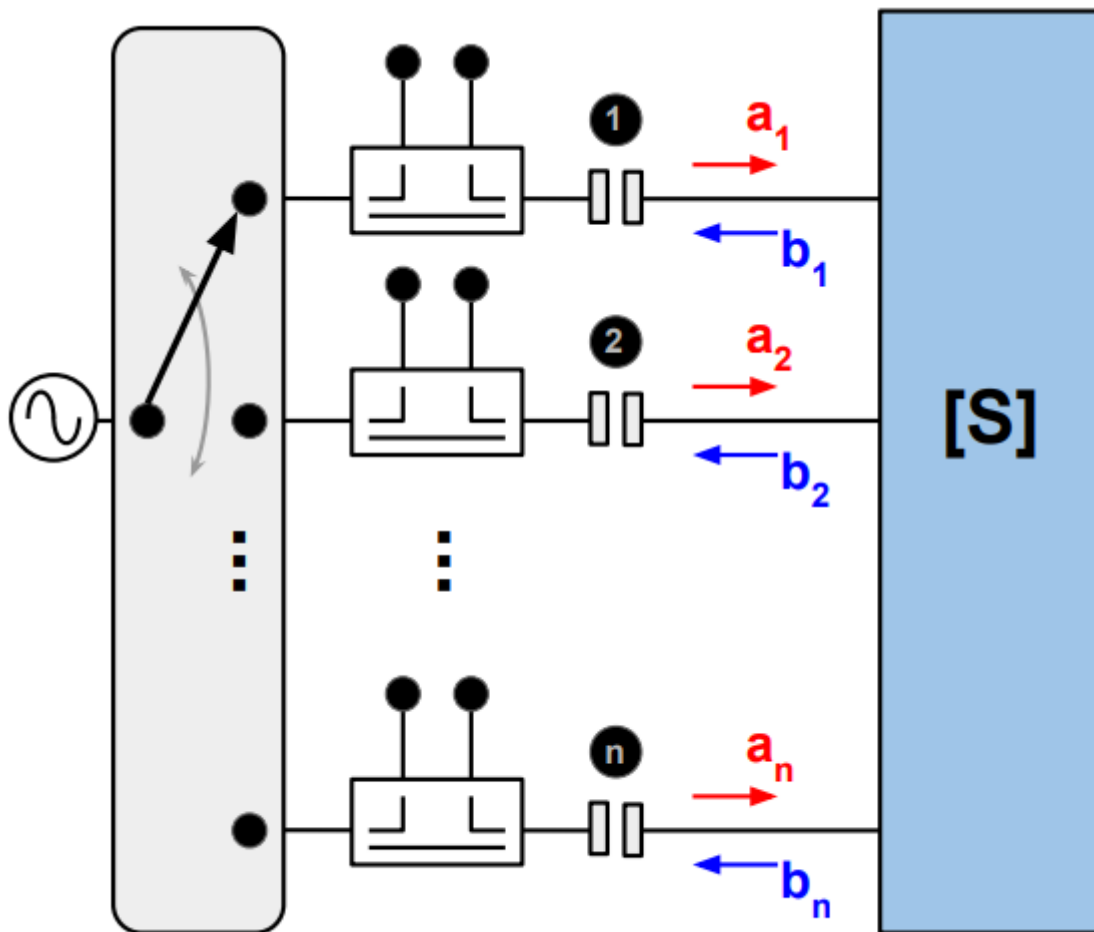

By definition :

$$[S] = \begin{bmatrix} b_{11} & \dots & b_{1n} \\ \vdots & \ddots & \vdots \\ b_{n1} & \dots & b_{nn} \end{bmatrix} \begin{bmatrix} a_{11} & \dots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \dots & a_{nn} \end{bmatrix}^{-1}$$

$a_{ij}$  : wave  $a$  at port  $i$  when the RF source is active on port  $j$

SOLR:  $[S]$  is unknown but reciprocal ( $S_{ij}=S_{ji}$ )

# SOLR for multiport NVNAs

Fully calibrated system:  $[S] = [b_{ij}] \cdot [a_{ij}]^{-1}$

Partially calibrated system:  $[\bar{S}] = [\bar{b}_{ij}] \cdot [\bar{a}_{ij}]^{-1}$

$$[S] = [\text{diag}(\alpha_1, \dots, \alpha_n)] [\bar{S}] [\text{diag}(\alpha_1, \dots, \alpha_n)]^{-1}$$

$$S_{ij} = \frac{\alpha_i}{\alpha_j} \bar{S}_{ij}$$

Reciprocity:  $S_{ij} = S_{ji}$

$$\alpha_j = \pm \alpha_i \cdot \sqrt{\frac{\bar{S}_{ij}}{\bar{S}_{ji}}}$$

The correct solution is selected according an estimation of  $\text{Arg}\{S_{ij}\}$

We start from  $\alpha_1 = 1$  and then calculate  $\alpha_i$  for  $i = 2..n$

# SOLR for multiport NVNAs

## The Dijkstra Algorithm

Example on a non-ideal multiport “thru” standard

$$\alpha_1 = 1$$

$$\alpha_2 = \pm \alpha_1 \cdot \sqrt{\frac{\bar{S}_{12}}{\bar{S}_{21}}}$$

$$\alpha_3 = \pm \alpha_1 \cdot \sqrt{\frac{\bar{S}_{13}}{\bar{S}_{31}}}$$

$$\alpha_4 = \pm \alpha_3 \cdot \sqrt{\frac{\bar{S}_{34}}{\bar{S}_{43}}}$$

**RF Paths**

Source: None

A: None

B: None

- Each port include its CalKit, RF power for calibration, Switch matrix configuration and physical source and receiver ports ;
- A NVNA is a unlimited array of predefined ports ;
- Once each port is SOL calibrated, “Thru” calibration require a SnP file for SOLT and SOLR.

## Measurement setups and calibration methods

- Scalar measurements with power meters ;
- Vectorial measurements with a multiport NVNA.

## Domain of Application

- Dual-input power amplifier analysis (Digital Doherty, Outphasing and LMBA)
- Beamformer behavioral modeling
- Nonlinear measurements for phased array antennas
